

Supplementary Fig. 1. The plasticome as a forest of fold groups. The 411 plasticome centroids in 56 sequence-similarity families (connected components at 30% identity over 50% coverage), grouped into 16 fold groups by the CATH superfamily of their catalytic domain. Each slice is one fold group with its own tree; slices are not related to each other. Tips are coloured by substrate; dashed lines are supported links between families of the same fold (not to scale). Structures show one representative enzyme per fold, with its CATH superfamily and PDB entry; LMC021 (AlphaFold DB) and PLAase I (ESMFold) are predicted models.
